Ensemble Learning

Dr. Faisal Kamiran

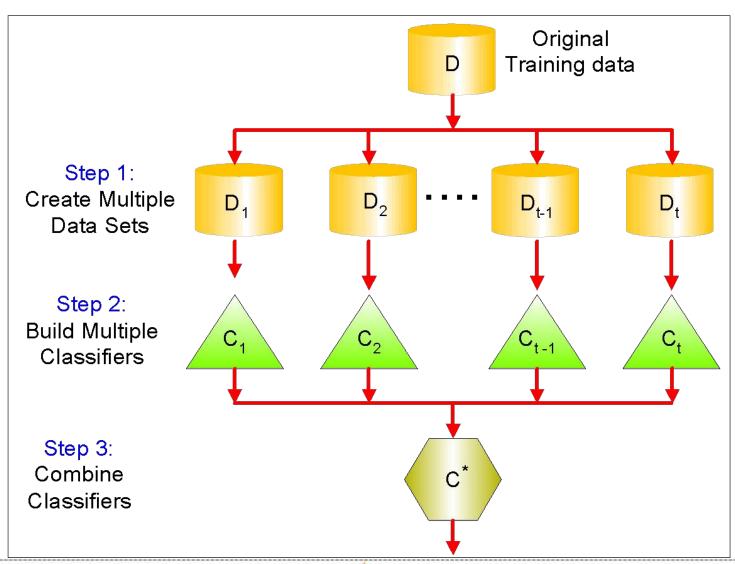

Ensemble Methods

Construct a set of classifiers from the training data

 Predict class label of previously unseen records by aggregating predictions made by multiple classifiers

General Idea

Why does it work?

- Suppose there are 25 base classifiers
 - Each classifier has error rate, $\varepsilon = 0.35$
 - Assume classifiers are independent
 - Probability that the ensemble classifier makes a wrong prediction by majority voting:

$$\sum_{i=13}^{25} {25 \choose i} \varepsilon^i (1-\varepsilon)^{25-i} = 0.06$$

Methods for Ensemble Classifiers

- By manipulating the training data:
 - Bagging
 - Boosting
- By manipulating the input features
 - Random forest
- By manipulating the class labels
 - Error correcting output coding
- By manipulating the learning algorithm

Bagging

 Create multiple samples of original data (almost of same size) with replacement

Original Data	1	2	3	4	5	6	7	8	9	10
Bagging (Round 1)	7	8	10	8	2	5	10	10	5	9
Bagging (Round 2)	1	4	9	1	2	3	2	7	3	2
Bagging (Round 3)	1	8	5	10	5	5	9	6	3	7

- Each sample, D_i, is called bootstrap sample
- Build classifier on each bootstrap sample

Bagging Algorithm

Algorithm 5.6 Bagging algorithm.

- 1: Let k be the number of bootstrap samples.
- 2: for i = 1 to k do
- 3: Create a bootstrap sample of size N, D_i .
- 4: Train a base classifier C_i on the bootstrap sample D_i .
- 5: end for
- 6: $C^*(x) = \underset{y}{\operatorname{argmax}} \sum_i \delta(C_i(x) = y)$. $\{\delta(\cdot) = 1 \text{ if its argument is true and } 0 \text{ otherwise}\}.$

Boosting

- An iterative procedure to adaptively change distribution of training data by focusing more on previously misclassified records
 - Initially, all N records are assigned equal weights
 - Unlike bagging, weights may change at the end of boosting round

Boosting

- Records that are wrongly classified will have their weights increased
- Records that are classified correctly will have their weights decreased

Original Data	1	2	3	4	5	6	7	8	9	10
Boosting (Round 1)	7	3	2	8	7	9	4	10	6	3
Boosting (Round 2)	5	4	9	4	2	5	1	7	4	2
Boosting (Round 3)	4	4	8	10	4	5	4	6	3	4

- Example 4 is hard to classify
- Its weight is increased, therefore it is more likely to be chosen again in subsequent rounds

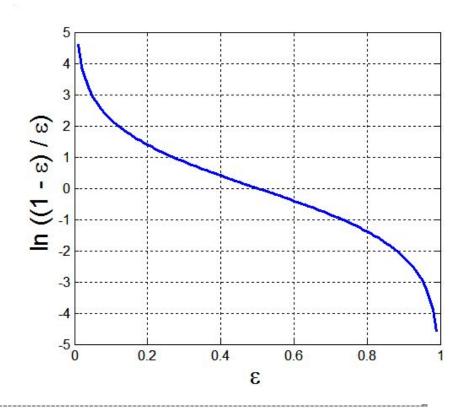

Example: AdaBoost

- Base classifiers: C₁, C₂, ..., C_T
- Error rate:

$$\varepsilon_{i} = \frac{1}{N} \sum_{j=1}^{N} w_{j} \delta(C_{i}(x_{j}) \neq y_{j})$$

Importance of a classifier:

$$\alpha_i = \frac{1}{2} \ln \left(\frac{1 - \varepsilon_i}{\varepsilon_i} \right)$$

Example: AdaBoost

Weight update:

$$w_i^{(j+1)} = \frac{w_i^{(j)}}{Z_j} \begin{cases} \exp^{-\alpha_j} & \text{if } C_j(x_i) = y_i \\ \exp^{\alpha_j} & \text{if } C_j(x_i) \neq y_i \end{cases}$$

where Z_i is the normalization factor

- If any intermediate rounds produce error rate higher than 50%, the weights are reverted back to 1/n and the resampling procedure is repeated
- Classification:

$$C*(x) = \underset{y}{\operatorname{arg max}} \sum_{j=1}^{T} \alpha_{j} \delta(C_{j}(x) = y)$$

AdaBoost Algorithm

Algorithm 5.7 AdaBoost algorithm.

- 1: $\mathbf{w} = \{w_j = 1/N \mid j = 1, 2, ..., N\}$. {Initialize the weights for all N examples.}
- 2: Let k be the number of boosting rounds.
- 3: for i = 1 to k do
- 4: Create training set D_i by sampling (with replacement) from D according to \mathbf{w} .
- 5: Train a base classifier C_i on D_i .
- 6: Apply C_i to all examples in the original training set, D.
- 7: $\epsilon_i = \frac{1}{N} \left[\sum_j w_j \, \delta(C_i(x_j) \neq y_j) \right]$ {Calculate the weighted error.}
- 8: if $\epsilon_i > 0.5$ then
- 9: $\mathbf{w} = \{w_j = 1/N \mid j = 1, 2, \dots, N\}$. {Reset the weights for all N examples.}
- Go back to Step 4.
- 11: end if
- 12: $\alpha_i = \frac{1}{2} \ln \frac{1 \epsilon_i}{\epsilon_i}$.
- 13: Update the weight of each example according to Equation given on the prev slide
- 14: end for
- 15: $C^*(\mathbf{x}) = \underset{y}{\operatorname{argmax}} \sum_{j=1}^T \alpha_j \delta(C_j(\mathbf{x}) = y)$.
